

Understanding Significant Polypharmacology in Chemical-induced Toxicity Using Toxcast and Tox21 Data

Samar Mahmoud

symm2@cam.ac.uk

s.mahmoud75@yahoo.com

22 Aug 19

Alternative approaches for toxicity assessment

Recent efforts shifted towards interpretable models which can explain the mechanistic background, helping in:

- Understanding mechanisms of toxicity
- Rationalizing decision making in toxicity assessment
- Prioritizing *in vitro* models for the relevant biological activities
- Variable, and slow, regulatory acceptance of black box QSAR models

QSAR models to predict chemical properties

Adverse outcome pathway framework is used for mechanistic interpretation of adverse effects

MIE: Molecular Initiating Event

KE: Key Event

AO: Adverse Outcome

By mining the statistical associations between changes at molecular and cellular level against toxicity in animal or human, we can generate hypothesis about mechanisms of toxicity

How data-based methods can be used to derive hypotheses about toxicity modes of action

Interpretable Features

Chemical Properties

- Physicochemical properties
- Structural alerts/Toxicophores

Biological activity

- Molecular
- Cellular
- Tissue/Organ

Interpretable Algorithms

- Correlation/association analysis
- Similarity over chemical or biological space (analogues)
- multivariate models (regression and decision trees)

Integrating clinical reports and *in vitro* data can be mined to derive mechanistic hypotheses

Information-Derived Mechanistic Hypotheses for Structural Cardiotoxicity

Fredrik Svensson,^{*,†,iD} Azedine Zoufir,[†] Samar Mahmoud,[†] Avid M. Afzal,[†] Ines Smit,[†] Kathryn A. Giblin,[†] Peter J. Clements,[‡] Jerome T. Mettetal,[§] Amy Pointon,^{||} James S. Harvey,[‡] Nigel Greene,[⊥] Richard V. Williams,[#] and Andreas Bender^{*,†,iD}

Compounds rarely have one single biological action and are rather characterized by polypharmacology profiles

AOP networks are useful to analyze interactions, but limited by incomplete information

C) Changes in AO Severity and associated AOP network motifs []

A. Topology examples

B. Analytics examples

The current challenge to fully utilize the AOP network framework is the **incomplete information about KE/MIE** linked by KER towards adverse outcomes

Toxicity is explained by combinations of features represented as chemical and bioactivity properties

***Each combination constitutes of one or more assay endpoint and can contain one or more chemical properties*

$l, m \in F$, where F : physicochemical properties or structural alerts

Data-based approach: Rules

Feature Space (chemical feature/activity in targets/assays)

RULE : If (E) is green AND (C) is green → then (L) is red

Entropy is a purity measure to construct trees/rules

$$Entropy = -0.5 \log_2 0.5 - 0.5 \log_2 0.5 = 1$$

Conventional rules do not respect direction of association

Assumption **Positive Activity in Assay (key event)**  **Toxicity**

Example

Mitochondrial impairment  Toxicity  **Biologically meaningful**

Not cytotoxic  Toxicity  **Biologically irrelevant**

Key Event Relationships (KERs) in Adverse Outcome Pathways are directional

Biologically meaningful information can be generated by controlling direction of data-derived associations

Assumption Positive Activity in Assay (key event)  Toxicity

Example

Mitochondrial impairment  Toxicity  Biologically meaningful

Not cytotoxic  Toxicity  Biologically irrelevant

Assay_i + *chemical property*

Assay_k + *chemical property*

...

 Toxicity

Direction of in vitro-in vivo association is essential for interpretability!

Two rule-based workflows are proposed to mine associations with constraints

- 1- Rule models on **continuous data inputs** via modification of conventional rule models
- 2- Rules models on **binary/categorical** variables using controlled emerging patterns

Approach 1: Rule Pruning is applied to satisfy directional association

Approach 2: Controlled Emerging Patterns using binary features

These represent frequent itemsets that are more common in one class in comparison to the other (discriminating itemsets)

The pattern can be composed of one or more discriminating features

Hypothetical dataset containing the pattern {a,c} emerging in D1.

data entry		properties			
D_1	1	<i>a</i>	<i>b</i>	<i>c</i>	<i>d</i>

and Valerie J. Gillet^{*,†}

J. Chem. Inf. Model. 2014, 54, 1864–1879

Example (1)

prioritizing hepatotoxic *in vitro* endpoints
(modified rules on continuous features)

Hepatotoxicity involves complex pathological pathways which are difficult to capture

In vitro models for hepatotoxicity have high specificity but **low sensitivity**

- Which bioactivities in lab are predictive of hepatotoxicity *in vivo*?
- How chemical properties affect the concordance between *in vitro* measurements and *in vivo* observations?

DATASET

ToxCast *in vitro* readouts in AC_{50}^*
~8000 compounds against over 800 assays

Open-Source Cheminformatics
and Machine Learning

29 calculated physicochemical properties
(lipophilicity, molecular weight, number of rings, etc.)

ToxRefDB rat liver observations
~900 compounds against 17 liver measurements
Discretized into LEL** of 15mg/kg/day and 500mg/kg/day

Data integration of multiple sources: ~6million data points of 673 compounds

* Concentration at half maximum activity

** Lowest Effect Level

Analysis performed using modified rule workflow

Average number of conditions per toxic rule in the original set

<i>Condition type in toxic rules</i>			
<i>Toxicity threshold</i>	<i>Active in an assay</i>	<i>Inactive in an assay</i>	<i>physicochemical</i>
15mg/kg/day	1	3.8	0.9
500mg/kg/day	1	3.6	0.6

Overall per rule, there is one positive bioactivity, four negative bioactivities and one physicochemical property. The abundance of inactive assay conditions and physicochemical conditions is slightly lower at toxicity threshold 500mg/kg/day.

Rule modification to improve interpretability

Original rule:

APR_HepG2_MitoMembPot_72h_up > 2.036928

Tox21_HSE_BLA_agonist_ratio > 2.40309

>> class toxic

Workflow overview

Rule modification

APR_HepG2_NuclearSize_24h_up {Active}
Strongest.basic.pKa <= 6.48

Hepatotoxic

Modifications makes rules simple and interpretable

i) By performance

Filter by coverage

Filter by balanced accuracy

This selection retains rules with top accuracy (above 70%) and high rule coverage (above 50 and 20 for 500mg/kg/day and 15mg/kg/day, respectively)

Rule prioritization

ii) By overall coverage of toxic compounds

The combination of top accurate rules, which represents 80% of all toxic compounds, is prioritized. This resulted in 34 and 20 rules at 500mg/kg/day and 15mg/kg/day, respectively

Clustering

Prioritized rules are clustered according to similarity in toxic compound coverage

Bioactivity space for different levels of toxic potency is similar

500 mg/kg/day

- At 15mg/kg/day, multiple assay combinations predictive for hepatotoxicity can be seen including CYP2C6 with VDR and CXCL-9 with ER agonists
- In response to xenobiotics, VDR directly induces the upregulation of CYP2C6. Hence, compounds that combine activity against CYP2C6 and upregulation of VDR are likely to cause hepatotoxicity
- Studies have shown links between ER agonists and CXCL9, at which estrogen-treated mice have shown a significant reduction in the expression of CXCL9, a cytokine associated with liver fibrosis

└ represent assays co-occurred in one rule

Physicochemical Properties Improve Translatability Of *In Vitro* Measurements Into *In Vivo* Outcomes

Number of rotatable bonds is associated with permeability

Molecular Properties That Influence the Oral Bioavailability of Drug Candidates

Daniel F. Veber,^{*,†} Stephen R. Johnson,^{‡,§} Hung-Yuan Cheng,^{||} Brian R. Smith,[⊥] Keith W. Ward,[⊥] and Kenneth D. Kopple^{‡,#}

Departments of Medicinal Chemistry, Cheminformatics, Computational Analytical and Structural Sciences, and Drug Metabolism and Pharmacokinetics, GlaxoSmithKline, 709 Swedeland Road, P. O. Box 1539, King of Prussia, Pennsylvania 19406-0939

Received January 9, 2002

Oral bioavailability measurements in rats for over 1100 drug candidates studied at SmithKline Beecham Pharmaceuticals (now GlaxoSmithKline) have allowed us to analyze the relative importance of molecular properties considered to influence that drug property. Reduced molecular flexibility, as measured by the number of rotatable bonds, and low polar surface area or total hydrogen bond count (sum of donors and acceptors) are found to be important predictors of good oral bioavailability, independent of molecular weight. That on average both the number of rotatable bonds and polar surface area or hydrogen bond count tend to increase with molecular weight may in part explain the success of the molecular weight parameter in predicting oral bioavailability. The commonly applied molecular weight cutoff at 500 does not itself significantly separate compounds with poor oral bioavailability from those with acceptable values in this extensive data set. Our observations suggest that compounds which meet only the two criteria of (1) 10 or fewer rotatable bonds and (2) polar surface area equal to or less than 140 Å² (or 12 or fewer H-bond donors and acceptors) will have a high probability of good oral bioavailability in the rat. Data sets for the artificial membrane permeation rate and for clearance in the rat were also examined. Reduced polar surface area correlates better with increased permeation rate than does lipophilicity (C log *P*), and increased rotatable bond count has a negative effect on the permeation rate. A threshold permeation rate is a prerequisite of oral bioavailability. The rotatable bond count does not correlate with the data examined here for the in vivo clearance rate in the rat.

15mg/kg/day		
Physicochemical condition	Error rate%	Frequency %
NumRotatableBonds <= 6	7.8 ± 3.2	35
NumHBD <= 0	9.2 ± 3.7	10
NumAliphaticRings <= 2	2.7 ± 0.3	10

Number of rings is associated with plasma protein binding

500mg/kg/day

Key factor : animal testing studies do not extrapolate well to human!

Data from animal testing can be used to infer molecular mechanisms of adverse effects in human

Troglitazone was withdrawn in 2000 due to hepatotoxicity

Troglitazone is labelled as toxic at 500mg/kg/day, but not at 15mg/kg/day

According to rules, troglitazone has more liabilities than 75% of toxic compounds at 500mg/kg/day and equal to average at 15mg/kg/day

Example (2)

Understanding Polypharmacology in Acute Toxicity
(controlled emerging patterns on binary features)

Possible mechanisms are complex and diverse

Hamm et al (2017) have suggested multiple routes for the mechanisms for acute toxicity as a result of the acute toxicity workshop in Maryland, USA in 2015

Selected mechanisms of acute toxicity.¹

MIE or upstream key event	Example stressor	Relevant AOP
GABA receptor inhibition	Fipronil	Binding to the picrotoxin site of ionotropic GABA receptors leading to epileptic seizures ^a
Sodium channel inhibition	Pyrethroids	Axonal sodium channel modulation leading to acute mortality ^b
Protein synthesis inhibition	Ricin	
Sodium-potassium ATPase inhibition	Digoxin	
Mitochondrial inhibition	2-Buten-1-ol, 1-thenyl-4,4,4-trifluoro-3-trifluoromethyl-	
Binding of benzodiazepine sites on GABA receptor	Tetrazepam	
Acetylcholinesterase inhibition	4-(Methylamino)-3,5-xylyl methylcarbamate	Acetylcholinesterase inhibition leading to acute mortality ^c
GSH depletion followed by covalent binding of reactive metabolite to cellular proteins	Acetaminophen	
Michael acceptor reaction	Acrolein	
Voltage-gated sodium channel inhibition	Sodium valproate	
NMDA receptor antagonism	Methadone	
Anticoagulation	Coumadin	
Dopaminergic D2 receptor antagonism	Thioridazine hydrochloride	

¹ This table provides an outline of the some of the known mechanisms involved in acute systemic toxicity along with prototypical initiators. In some cases, the exact molecular initiating event (MIE) isn't known. Examples of adverse outcome pathways (AOPs) under development in the OECD AOP Wiki are noted and can be found on the web: a) <https://aopwiki.org/wiki/index.php/Aop:10> b) <https://aopwiki.org/wiki/index.php/Aop:96>; c) <https://aopwiki.org/wiki/index.php/Aop:16>.

By mining the multi-conditional associations between potential MIEs and KEs against toxicity outcomes, we can generate hypothesis about significant polypharmacology

Data

PubChem

☐ Toxicity data:

- **Globally Harmonized System:** acute oral toxicity PubChem class 1,2 and 3 are considered toxic, whereas classes 4 and 5 are non toxic

☐ Bioactivity data:

- i) **Tox21** %activity (~9000 compounds of ~900,000 data experimental data points)
- binned into > 20, >40 >60, >80) ~ 4million data points
- ii) **PIDGIN** (in-house tool for target prediction) annotated targets ~ 1800 for

☐ Substructures

- i) **ToxAlerts** using OCHEM server ~2300
- ii) **Frequent substructure** using MoSS in KNIME ~ 450
- **Data integration:** ~7,5million data points of ~2000 unique compounds almost balanced toxicity label

Nitroso compounds		-2.50

Cytotoxicity and toxicophores showed the strongest univariate associations

Synergy analysis to understand polypharmacology

- **1) Synergy using mutual information**
 - For $c = \{a, b\}$ pair in Rule i against toxicity label Z
 - **Synergy** = $MI(c_i, Z) - [MI(a_i, Z) + MI(b_i, Z)]$
 - **Improvement** = $MI(c_i, Z) - \max[MI(a_i, Z), MI(b_i, Z)]$
- **2) Synergy Factor from odd ratios (equivalent to interaction weight in regression equation)**
 - **Synergy Factor** = $OR_{12} / (OR_1 \times OR_2)$

Synergistic pairs are dissimilar in their chemical profiles and biological function

Known key events in acute toxicity show synergy with disruption of TR, VDR and AhR

Key Event	Frequently associated Key Events	Odd Ratio comb	Synergy factor	N# toxic compounds	Interpretation from literature
Androgen antagonism Estrogen antagonism	Six-member ring heterocycles	6.5 2.9	3.8 1.5	37 47	Heterocycles steroids have enhanced activity and can produce neurotoxicity and convulsions
Glutamate receptor	<u>TR antagonism</u>	3.7	2.2	46	Thyroid hormone activates glutamic neuronal reuptake. Mitochondrial toxicity potential toxicity of glutamate disruptors.
	Cell viability	3.9	2.0	37	
	Disruption of mitomembrane potential	2.4	1.5	68	
GABA receptor	ARE agonist	21.7	6.8	21	TR and ROS control GABA reuptake. Vitamin D3 via VDR regulate GABA expression.
	<u>TR antagonism</u>	22.8	5.4	21	
	Disruption of mitomembrane potential	23.8	6.1	22	
		5.8	2.5	23	
		2.4	1.4	62	
	HIF2 <u>VDR</u>				

Known key events in acute toxicity show synergy with disruption of TR, VDR and AhR

Cyp2C19	CAR antagonism	1.4	1.0	327	CAR, VDR and AhR regulate the expression of Cytochrome P enzymes.
	<u>VDR antagonism</u>	1.5	1.1	308	
	<u>AhR activation</u>	1.5	0.9	326	
AChE	Derivatives of carbamates	17.4	4.9	17	Depletion of PIP2 mediated the inhibition of ACh K ⁺ ion channels via PI5P4K inhibition. Cholinergic toxidrome involve Ca ion dysregulation and inflammation. Interference with calcium sensitization of troponin and inflammatory responses of NLRP3 are associated with cardiovascular effects.
	Phosphatidyl inositol 5 phosphate kinase	6.4	2.6	37	
		1.8	1.2	164	
	<u>VDR antagonism</u>	1.8	1.1	141	
	<u>AhR activation</u>	1.6	1.0	243	
	Troponin T cardiac NLRP3	1.7	1.0	233	
Nitric Oxide Synthase (NOS)	Retinal	2.1	1.3	99	VDR and retinal dehydrogenase activities can induce NOS expression.
	dehydrogenase	2.0	1.2	160	
	<u>VDR</u>	3.2	1.2	61	
	Alkyl halides				

Analysis of rule networks can reveal interesting patterns

Rule networks show mechanisms-based clustering

Specific and non-specific pathway perturbations form **independent clusters**.
Therefore, analysis of key events acute toxicity should consider both

Known key events in acute toxicity were central in rule networks

Structural alerts		Bioactivity features	
	<i>Top degree</i>	<i>Top NMI</i>	
<i>Custer 1</i>	- six membered heterocyclic compounds - C=O - C=N - halogen derivatives - nitrile - saturated heterocycles - nitrogen linked to saturated carbon chain - α,β-unsaturated bond linked to oxygen atom (Michael rection acceptor)	- oxygen- linked to aliphatic carbon chain (variable length) - nitrogen linked to saturated carbon chain (variable length)	- TR (antagonist) - NFE2 - CAR (antagonist) - Glutamate receptor (ion channel) - Disruptors of mitochondrial memberane potential - SIR2 - Cell viability
			- ARE (agonist) - CAR (antagonist) - ER (antagonist) - AR (antagonist) - Cell viability
<i>Custer 2</i>	- Halogens - Aromatic amines - N - Amines - Oxygen group (O,S,SE)	- Halogenated alkyls and allyls - N and S mustard - O	- AhR - Troponin T cardiac - VDR(antagonists) - NOS - AMPK - AChE - MAP kinase kinase
			- DAO - Neuronal Ach - Tyrosine kinase - TYRO3 - AChE - Serine threonine protein kinase - NOS
<i>Custer 3</i>	- Pnictogen (N group) - Carboxylic acid derivatives - Tertiary amine - P or S - Derivatives of urethane (carbamates)	- <u>Thiophosphoric acid derivatives</u> - P - N-substituted anilines - Pnictogens (N-group) - Benzyl amine	- Ephrine type A receptor - Ca calmodulin protein kinase - Cyclic phosphodiesterase - AhR (activator) - AChE - PIPK
			- Cyclic phosphodiesterase - Carboxic acid ester hydrolase

Nuclear receptor
Disruption on their own
may not explain how
acute toxicity was
triggered. Because they
are related to chronic
effects.

Exploring polypharmacology is important especially at low potencies

Degree connectivity is associated with how frequent the feature is used in the rules. There is an inverse relationship between potency in Tox21 assay and connectivity in the network

Visualizing compound-specific rule networks help to navigate polypharmacology and assess risk

Toxic compounds

Overactivation of cytotoxicity cluster

Non-toxic compounds

Weak activation of network clusters

Toxic compounds

Higher density of synergistic links
(synergy density greater than 15%
has 3.5 higher odds to observe
acute toxicity)

Non-toxic compounds

Promiscuous compounds of relatively lower density of
synergistic links (compared to toxic compounds of similar
substructures)

Conclusions

- **Hepatotoxicity** cannot very well be captured by single assay endpoints, but better by a **combination of bioactivities in relevant assays**, with the likelihood of hepatotoxicity increasing with **assay promiscuity**
- *In vitro-in vivo* associations improved by incorporating physicochemical properties, such as number of rotatable bonds, especially for the potent toxicity levels
- In order to capture **acute toxicity** using *in vitro* methods, **polypharmacology** should be considered, especially **at weak potencies** which can be overlooked using conventional safety margin methods
- **Synergistic polypharmacology** is common between known key events and the disruption of relevant nuclear receptors (**TR, VDR and AhR**)
- Understanding significant polypharmacology can be used to guide cost and time effective iterative screening protocols for toxicity assessment
